Abstract

In the fight against climate change, renewable energy has been subsidised in many countries. With the costs passed onto consumers, governments are paying those, for example, who instal domestic solar panels on top of their homes and feed electricity back into the system at preferential rates. We know that substantial amounts of income flow into households with solar installations as a result, but we do not know much about the political consequences of these programmes. Similar government programmes are known to have resource and interpretative effects on participants, leading to changes in their attitudes. Drawing on three longitudinal surveys from Germany, United Kingdom, and Switzerland, this article analyses whether installation of these solar panels causes meaningful changes in households' various political attitudes. Using fixed-effect models as the identification strategy, the article reports null results – solar installations do not seem to generate political attitudes. This is good as well as bad news for actors looking to increase the amount of renewable energy produced through solar installations.

Keywords

policy feedback, political attitudes, climate policy

Accepted: 19 August 2021

Introduction

Policies to fight climate change have created a new kind of energy producer – households with solar installations on their roof. In addition to the subsidies available for households to instal solar panels, in many countries, they can also feed electricity back into the system at preferential rates. With the the costs passed onto the energy consumers, solar installations are essentially redistributive mechanisms. Indeed, evidence shows that substantial amounts of income flow into households with solar installations (Winter and Schlesewsky, 2019).

This article analyses whether individuals develop distinct political attitudes as a result of living in households with solar panels over time. Political scientists have long been interested in policy feedback – how the policies of today might affect the politics of

tomorrow through changes in, among others, political attitudes. Béland (2010), Campbell (2012) and Larsen (2019) provide systematic reviews of the resulting literature, going as far back as to Schattschneider (1935), with the central argument that ‘new policies create new politics’ (Schattschneider, 1935: 288). Accordingly, public policies, once implemented, shape the politics that create them in the first place.

Pierson (1993) suggests that there might be two mechanisms behind policy feedback on political attitudes among the public. First, policies might alter the allocation of resources in a society, and therefore affect the ability and/or motivation of political actors to get involved in the following political processes. For example, if solar installations generate income, individuals living in solar households will have increased resources – not only money but also time – to be informed about politics. They will also have the motivation to do so because their new income depends on a government programme, and they have a stake in how that programme would look in the future. Similar effects have been recorded elsewhere, such as the Social Security programme in the United States. Campbell (2003) shows that with additional income and early retirement, the recipients of the programme become politically active, which is especially true for the recipients from low-income groups.

Second, public policies might have interpretive effects, changing the way people perceive the world around themselves. In this sense, households with solar installations are likely to learn more about not only the specific government programme but also related issues such as energy transition and climate change. As a result, they might develop political attitudes. For example, Soss (1999) shows that the participants of badly administered programmes can develop mistrust towards governments, taking cues from their interactions with civil servants.

Nevertheless, we know very little about the potential feedback from solar installations. In a recent study, Mildemberger et al. (2019) find that political participation is higher among the members of households with, compared to without, solar installations in the US. The differences between the two types of households are substantively large, with six to nine percentage points higher proportion of solar households voting in elections (Mildemberger, Howe, and Miljanich, 2019: 3). What remains unknown is whether solar installations are the cause of such politically consequential differences. Comparison of households with and without solar panels might be misleading to answer this question, as these groups are likely different from one another in many aspects, some of which might account for the differences in political attitudes – a common problem in the policy feedback literature, with high concerns for reverse causality and omitted variable bias (Campbell, 2012; Larsen, 2019).

Using three panel datasets with repeated measures on households, this article offers a more plausible comparison: changes in political attitudes within individuals over a period of years, between those who start or stop living in a household with solar panels and those whose status do not change during that period. The results show no signs of meaningful effect of solar installations on political attitudes. Individuals living in solar households do not become more or less interested in politics. Neither do they experience a change in their political position, trust in government or party identification.

Data and Estimation Strategy

To test whether installation of solar panels causes meaningful changes in households’ various political attitudes, I looked for any publicly available, longitudinal study with

measures on (a) solar panel ownership, (b) political attitudes and (c) demographic indicators. Three studies met these criteria well: the German Socio-Economic Panel (SOEP), the UK Household Longitudinal Study (UKHLS) and the Swiss Household Panel (SHP). Although the resulting case selection depends on data availability, the credibility of the claims in this analysis is somewhat higher due to the fact that they are based on data from not one but three countries.

Each of these panels is a widely used source of data on households, whose members are surveyed repeatedly over time.¹ All three datasets include measures of political attitudes as well as demographic indicators, which I use as dependent and control variables, respectively. What makes this selection particularly useful for this study, however, is that these datasets also include indicators for solar panel ownership, the key variable of interest in this study.

The time period varies from one case to another, depending on the survey waves that include the necessary indicators for solar panel ownership. In the SOEP, this occurs in each of the 11 waves between 2007 and 2018, as respondents in these waves are asked whether their dwelling has ‘solar collector, solar energy system’ or not. In the UKHLS, this variable is available for three waves (2008–2009, 2009–2011 and 2012–2014),² in which respondents were asked whether they have installed solar panels for electricity or water heating. For these two datasets, I code *Solar Panelit* as equals to 1 if an individual i lives in a dwelling with any kind of solar system at time t .

The coding of this variable is less straightforward for the SHP. Beginning with 2013, the household part of the survey indicates whether dwellings have been renovated with solar panels during the previous year. Assuming that once a dwelling is renovated with solar panels, these panels stay in place, I code *Solar Panelit* as 0 if a dwelling has not been renovated with solar panels, as 1 for the renovation year and every year after that until 2018, the latest available wave. To support this assumption, I limit the analysis to those households who have not moved since 2013.

The resulting dataset has 322,309 person-year observations in Germany (68,573 respondents from 39,149 households), 112,570 in the UK (72,869 respondents from 63,988 households) and 79,131 in Switzerland (19,234 respondents from 7885 households).

In terms of outcomes, I focus on a variable that is common across all three datasets for the main part of the analysis: *Political Interest*. This variable measures how interested respondents are in politics, originally with a 5-point scale in the SOEP and UKHLS but with an 11-point scale in the SHP. I have rescaled the variable in the SHP to facilitate comparisons across the cases. As I will also show, the results from this dependent variable do not change if the analysis is on various other variables, including left-right position, trust in government or party identification.

Simple comparisons of political attitudes between those who live in a dwelling with and without solar systems are likely to be misleading. First, there might be systematic differences between these two groups of people, and these differences might affect both solar system adoption and political attitudes. For example, research shows that solar systems are more likely to be adopted by people with high income and high environmental concerns (Jacksohn et al., 2019). At the same time, such characteristics can lead to certain political attitudes. Second, some other important factors, while constant for all individuals, would vary over time. These include, for example, the amount of subsidies of feed-in-tariffs available for solar systems. Similarly, we might observe variations in political attitudes over years, such as increases in political interest in election years.

One way to address these concerns is to use linear fixed-effects regressions in the form of

$$Y_{it} = \beta_1 \times \text{Solar Panel}_{it} + \lambda_i + \delta_t + \epsilon_{it} \quad (1)$$

where β_1 is the causal effect of interest – the effect of solar system ownership on political attitudes, based on within-individual variation associated with starting and/or stopping to live in a dwelling with a solar system during the periods under analysis. In this setting, λ_i accounts for individual characteristics that do not change over time, while δ_t accounts for changes that evolve from one year to another but are constant across individuals.

I also estimate models with covariates in the form of

$$Y_{it} = \beta_1 \times \text{Solar Panel}_{it} + \lambda_i + \delta_t + \theta \times X_{it} + \epsilon_{it} \quad (2)$$

where X_{it} is a vector of controls for education, head of households, unemployment, household income, households with children, home owners and geographical regions.

Results

Table 1 presents the regression models of political interest, three models for each country. The first models for each country (Models 1, 4 and 7) are calculated with pooled data – by pooling all individuals across time, without any fixed-effects. For Germany and the UK, the coefficients for *Solar Panel* describe the differences in political interest between those who live in households with solar panels and those who do not. For Switzerland, the comparison is with those who had not acquired solar panels after 2013, who may or may not have renovated their house with solar panels before that year. These coefficients are positive, relatively large, and in the case of Germany and the UK, they are statistically significant. Nevertheless, these results suggest that overall people with solar panels are interested in politics more than those in the comparison groups. In the UK, for example, the differences are about a sixth of a point, over a 4-point scale.

These results, however, are likely to be biased. Those who decide to have solar panels are probably different than those who do not, in various observable and unobservable ways. Moreover, the results from pooled models do not reveal the direction of causality: is political interest causing people to acquire solar panels, or is living in a house with solar panels making people more interested in politics? The fixed-effects models, as specified in Equation 1, are an attempt to address these problems, as these models limit the analysis to within-individuals, comparing changes in individuals that experience a change with regard to solar panels (starting and/or stopping to live in a house with solar panels) to those individuals for whom the solar panel ownership remains constant (i.e. they have always or never lived in solar households during the periods under analysis).

Indeed, when fixed-effects are introduced (Models 2, 5, and 8), we observe a considerable change in the results, compared to the pooled estimates. First, the point estimates become much smaller. In comparison to the pooled models, where the coefficients range between 0.09 and 0.17, with fixed-effects these are reduced to a range from -0.02 to 0.01 . These results suggest that after starting to live in a household with solar panels, people might become slightly less as well as slightly more interested in politics. These changes are not only substantively small but also statistically insignificant.

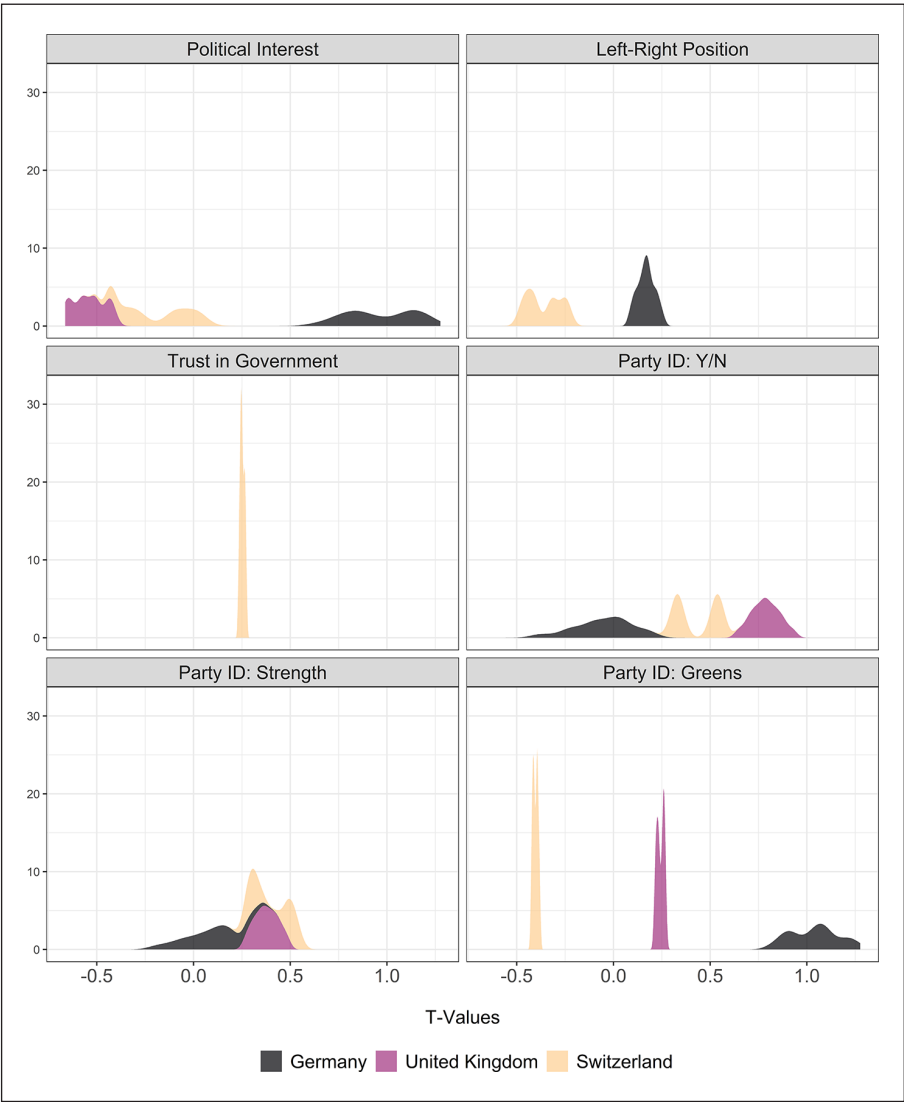

Figure 1. Distribution of t Values from Sensitivity Analyses.

In addition to fixed-effects, the final models of each country include seven control variables as well, controlling for various individual- and household-level factors that change over time, such as household income, as specified in Equation 2. The overall results remain the same: If solar panels affect how much residents in a household are interested in politics, this change is a substantively and statistically insignificant one.

Sensitivity Analyses

How sensitive are these results to the selection of dependent and control variables? *Political Interest* is only one of the several alternative measures of political attitudes. Would the results change if we analyse a different measure of political attitude? Similarly,

the preferred models include all seven control variables together to reduce selection bias, but the results might change if one or more of these control variables are excluded. Therefore, as a sensitivity analysis, I first gather five additional dependent variables from the three datasets, and regress all dependent variables on the mathematical power set of seven control variables. Note that not all dependent variables are available in all three datasets. This exercise results in 1920 regression models.

Figure 1 plots the t values from all possible regression models. In the upper-left box, we see that the results presented in Table 1 are robust to inclusion or exclusion of any of the control variables in the final models: all t values are smaller than 2 in absolute value, indicating that the change in *Political Interest* among people who start living under a solar panel is not significantly different from zero than people who experience no such change in their life.

The null results persist for other dependent variables as well. For example, in comparison to respondents who do not acquire solar systems during the time period under analysis, those who do become slightly more or less right-wing, but these changes are not statistically significant. The same is also true if we look at how much these respondents trust in their government or whether and how much they identify with a political party.

A final dependent variable measures political attitudes towards green parties. If solar panels cause changes in environmental attitudes, we are more likely to observe changes in political attitudes towards green parties – parties that own environmental issues. Moreover, solar panels are likely to be more economically beneficial for the owners under a green-party government. However, I find that solar panel ownership does not affect political attitudes towards green parties either: respondents with solar panels are not significantly more likely to identify with green parties. This could be because the solar panel ownership does not seem to change environmental attitudes in the first place, as I show in the Supplemental Appendix.

Conclusion

Do solar installations have feedback on political attitudes? Individuals living in households with solar installations participate in government programmes with potentially high resource and interpretative effects. The policy feedback theory would therefore predict these individuals to experience changes in terms of attitudes.

To test whether solar installations have feedback over time, I analysed data from three household panels from Germany, Switzerland, and the United Kingdom. This allows testing for any significant changes in political attitudes within individuals over a period of years. Specifically, I compare the attitudes of those who start or stop living in a household with solar panels with those whose ownership status do not change during that period.

The results do not support the expectation that solar installations might have effects on political attitudes. I find that solar installations do not make residents more or less interested in politics – a result that holds if we control for various factors or analyse a set of different outcomes. The latter include respondents' left-right positions, trust in government and party identification. This is good as well as bad news for actors looking to increase the amount of renewable energy produced through solar installations.

On one hand, it is good news as solar installations with no feedback are less likely to attract opposition from political elites on the losing side of the debate. If individuals living in solar households started identifying with a certain party – say, the green parties – this would create incentives for other parties to oppose the renewable energy programmes for domestic solar energy production.

On the other hand, some might consider the null results as a missed opportunity. One potential outcome of policy feedback is the lock-in effect (Pierson, 1993), where beneficiaries of government programmes act as a political force to consolidate these programmes. If solar installations increased households' political interest and made them act together for their interest, this could have created incentives for political leaders to invest further resources in solar energy. However, the results in this article suggest that solar installations do not have such effects.

Online Appendix to

‘Solar Panels and Political Attitudes’

Descriptive Statistics

Table A1 presents the summary statistics, by survey wave, for all variables in the main text—except for *Region*, which is a categorical variable. The column *Original* lists the item names in the original datasets that I use to create the variables, for which I provide brief descriptions below. For further details, please see the documentation of the original datasets.

Dependent Variables

Political Interest

- SOEP:
 - Item: ‘Generally speaking, how interested are you in politics?’
 - Note: The answer categories—‘Very interested,’ ‘Moderately interested,’ ‘Not interested,’ and ‘Disinterested’—are reverse coded so that higher values indicate increasing interest (i.e., ‘Disinterested’ = 1 ... ‘Very interested’ = 4).
- UKHLS:
 - Item: ‘How interested would you say you are in politics?’
 - Note: The answer categories—‘Very Interested,’ ‘Fairly interested,’ ‘Not very interested,’ and ‘Not at all interested’—are reverse coded so that higher values indicate increasing interest (i.e., ‘Not at all interested’ = 1 ... ‘Very interested’ =

4).

- SHP:
 - Item: ‘Generally, how interested are you in politics, if 0 means “not at all interested” and 10 “very interested?”’
 - Note: This variable has been rescaled to range from 1 to 4.

Left-Right Position

- SOEP:
 - Item: ‘In politics, people often talk about “left” and “right” when describing different political views. When you think about your own political views, how would you rate them on the scale below? 0: far left, 10: far right.’
- SHP:
 - Item: ‘When they talk about politics, people mention left and right. Personally, where do you position yourself, 0 means “left” and 10 “right?”’

Trust in Government

- SHP:
 - Item: ‘How much confidence do you have in the federal government (in Bern), if 0 means “no confidence” and 10 means “full confidence?”’

Party ID: Y/N

- SOEP:
 - Item: ‘Do you lean towards a particular party?’
 - Note: This variable is coded as 0 for ‘No,’ as 1 for ‘Yes.’
- UKHLS:
 - Item: ‘Generally speaking do you think of yourself as a supporter of any one political party?’
 - Note: This variable is coded as 0 for ‘No,’ as 1 for ‘Yes.’

- SHP:
 - Item: ‘Overall, do you feel close to any political party?’
 - Note: This variable is coded as 0 for ‘No,’ as 1 for ‘Yes.’

Party ID: Strength

- SOEP:
 - Item: ‘To what extent?’
 - Notes. First, the answer categories are reverse coded so that the higher values indicate increasing strength (i.e., ‘Very weakly’ = 2 ... ‘Very strongly’ = 6). Then, I have added the code 1 for respondents that do not support any party (i.e., *Party ID* = 0).
- UKHLS:
 - Item: ‘Would you call yourself a very strong supporter of [the party that you support], fairly strong or not very strong?’
 - Notes: First, the answer categories are reverse coded so that the values indicate increasing strength (i.e., ‘Not very strong’ = 2 ... ‘Very strong’ = 4). Then, I have added the code 1 for respondents that do not support any party (i.e., *Party ID* = 0).
- SHP:
 - Item: ‘Do you feel “very close” to this party, “quite close” or “not very close?”’
 - Notes: First, the answer categories are reverse coded so that the values indicate increasing strength (i.e., ‘Not very close’ = 2 ... ‘Very close’ = 4). Then, I have added the code 1 for respondents that do not support any party (i.e., *Party ID* = 0).

Party ID: Greens

- SOEP:
 - Item: ‘Which party do you lean toward?’

- Notes: This question is asked only if respondents support a party (i.e., *Party ID* = 1). I code this variable as 1 if they support Alliance90/The Greens, and as 0 if (a) they do not support any party (i.e., *Party ID* = 0) or (b) they support a party other than Alliance90/The Greens. A small number of respondents indicate more than one party. In such cases, I code this variable as 1 if one of these parties are Alliance90/The Greens.
- UKHLS:
 - Item: ‘Which political party do you support?’
 - Notes: This question is asked only if respondents support a party (i.e., *Party ID* = 1). I code this variable as 1 if they support the Green Party, and as 0 if (a) they do not support any party (i.e., *Party ID* = 0) or (b) they support a party other than the Green Party.
- SHP:
 - Item: ‘Which party do you have in mind?’
 - Notes: This question is asked only if respondents support a party (i.e., *Party ID* = 1). I code this variable as 1 if they support the Green Party of Switzerland, Socialist Green Alternative, or the Green Liberal Party of Switzerland, and as 0 if (a) they do not support any party (i.e., *Party ID* = 0) or (b) they support a party other than the three green parties in Switzerland.

Independent Variable

Solar Panel

- SOEP:
 - Item: ‘What amenities does your dwelling have?’
 - Note: This variable is coded as 1 if respondents indicated that their household have a ‘Solar collector, solar energy system.’ Otherwise it is coded as 0.
- UKHLS:

- Items: ‘Have you installed or are you seriously considering any of the following...’; ‘solar panels for electricity?’ ‘Solar water heating?’
- Note: This variable is coded as 1 if respondents answered ‘Yes — fitted’ to either of the questions above. Otherwise it is coded as 0.
- SHP:
 - Item: ‘Have you or your landlord done any larger modernizations in the flat since [month-year]? ... What kind of renovations have been made?’
 - Notes: ‘month-year’ refers either to the date the households were last surveyed in the previous year (for existing households) or to a date 12 months earlier (for new households). I have coded this variable as 0 if respondents replied ‘No’ to solar-panel modernisations. If they replied ‘Yes,’ I have coded this variable as 1 for that survey wave *and* for any other wave that follows.

Control Variables

Education

- SOEP:
 - Item: ‘ISCED-1997-Classification’
 - Note: This variable ranges between ‘In school’ = 0 to ‘Higher education’ = 6.
- UKHLS:
 - Item: ‘Current status: highest educational or vocational qualification’
 - Note: This variable is reverse coded so that it ranges between ‘No qualification’ = 1 and ‘University degree’ = 6.
- SHP:
 - Item: ‘International standard classification of education ISCED 1997’
 - Note: This variable has been recoded to range between ‘Not completed primary (compulsory) education’ = 0 to ‘Second stage of tertiary education’ = 9.

Head of Household

- SOEP:
 - Item: ‘Relationship to the head of household’
 - Note: This variable is coded as 1 for the answer category ‘Head Of HH, Contact Person,’ as 0 for other household members.
- UKHLS:
 - Items: ‘Conventional head of household indicator’ (Wave 2008-2009); ‘Household reference person’ (Waves 2009-2011 and 2012-2014).
 - This variable is coded as 1 for respondents who are ‘Head of household’ (Wave 2008-2009) or ‘Reference person’ (Waves 2009-2011 and 2012-2014). Otherwise it is coded as 0.
- SHP:
 - Item: ‘Relation to the person of reference’
 - Note: This variable is coded as 1 for ‘Reference person,’ as 0 for other household members.

Unemployed

- SOEP:
 - Item: ‘Occupational status’
 - Note: This variable is coded as 1 if respondents are ‘Unemployed, Not Employer.’ Otherwise it is coded as 0.
- UKHLS:
 - Item: ‘Which of these best describes your current employment situation?’
 - Note: This variable is coded as 1 if respondents are ‘Unemployed.’ Otherwise it is coded as 0.
- SHP:
 - Item: ‘Working status’

- Note: This variable is coded as 1 if respondents are ‘Unemployed.’ Otherwise it is coded as 0.

Household Income

- SOEP:
 - Item: ‘Monthly household net income’
- UKHLS:
 - Items: ‘Annual household net income’ (Wave 2008-2009); ‘Monthly household net income’ (Waves 2009-2011 and 2012-2014)
 - Note: For the Wave 2008-2009, I have divided the annual household net income into 12 so that all values refer to monthly income.
- SHP:
 - Item: ‘Yearly household income net’
 - Note: I have divided the original values into 12 so that all values refer to monthly income.

Household with Children

- SOEP:
 - Item: ‘Children under 16 years in household’
 - Note: This variable is coded as 1 if there are one or more children under 16 years in household. Otherwise it is coded as 0.
- UKHLS:
 - Item: ‘Number of children in household’
 - Note: This item counts the children aged 15 or under. I have coded this variable as 0 for households with no children. Otherwise it is coded as 1.
- SHP:
 - Item: ‘Number of children in household: 0 to 17 years’
 - Note: This variable is coded as 1 for households with one or more children.

Otherwise it is coded as 0.

House Owned

- SOEP:
 - Item: ‘Tenant or owner of dwelling’
 - Note: This variable is coded as 1 for owners. Otherwise it is coded as 0.
- UKHLS:
 - Item: ‘Does your household own this accommodation outright, is it being bought with a mortgage, is it rented or does it come rent-free?’
 - Note: This variable is coded as 1 for properties that are owned, owned with mortgage, or those that involve shared ownership. Otherwise it is coded as 0.
- SHP:
 - Item: ‘Are you, or another person living in your household, a tenant or owner of the accommodation you currently live in?’
 - Note: This variable is coded as 1 for those indicating ‘Owner/co-owner.’ Otherwise it is coded as 0.

Region

- SOEP:
 - Item: ‘NUTS-systematic-1 (federal state)’
 - Note: This is a categorical variable, with 16 levels. It refers to the *NUTS 1* regions of Germany.
- UKHLS:
 - Item: ‘Government office region’
 - Notes: This is a categorical variable, with 12 levels. It refers to the *NUTS 1* regions of the UK.
- SHP:
 - Item: ‘Region of residence’

- Note: This is a categorical variable, with 7 levels. It refers to the *NUTS 2* regions of Switzerland.

Would the null results change if we analyse relevant subgroups, such as those who live in a house that they own or those who are heads of households? These groups of individuals are more likely to benefit, and therefore be affected, from living in a house with solar installations. To explore the possibility that the results might be heterogeneous with regard to these factors, I estimate interactions effects, between *Solar Panel* and *House Owner* (Table A2) and between *Solar Panel* and *Head of Household* (Table A3), for each of the three models in Table 1.

The results show no signs of heterogeneity, with the interaction terms returning substantively and statistically insignificant estimates in all models. This suggests that the null results continue to hold if we limit the analysis to house owners or tenants, heads or other members

of households.

Solar System Types

There are two main types of solar systems: solar photovoltaic (PV) and solar thermal (ST). PV systems produce electricity, which can be consumed in the dwelling and/or fed back into the electricity grid for compensation from the utility. In comparison, ST systems turn sunlight into heat, providing warm water or space heating for the dwelling. It is also possible to have both systems on the same rooftop.

One concern is that the effects of solar systems might be heterogeneous, depending on the type of solar systems that households have on their rooftop perhaps because they generate different amounts of revenues. For example, Jacksohn, Grösche, Rehdanz, and Schröder (2019) show that, in Germany, PV systems used to generate almost twice as much revenue for households than ST systems in 2008, but this has been reversed in the recent years.

While the information on the type of solar systems is available for all three UKLHS waves used for the analysis, it is only available for the 2015 and 2016 waves in the SOEP. For SHP, this information is not available at all. Nevertheless, I repeat the models in Table 1 with the data available, differentiating between the types of solar systems. The results, as presented in Table A4, are similar: those who live in households with solar installations are significantly more interested in politics (Models 3 and 6), irrespective of the solar system type. However, these effects disappear with the fixed-effects: if we limit the analysis to within persons, and remove any changes common to all individuals from one survey wave to another, there is no meaningful effect of solar panels on political interest (Models, 2, 3, 4, and 6).

Table A4: Effect of different types of solar systems on political attitudes

	Germany (1 - 3)			United Kingdom (4 - 6)

Environmental Attitudes

Does solar panel ownership affect environmental attitudes? There is a mounting evidence (see the literature review by Nilsson, Bergquist, and Schultz, 2017) that engaging in one environmental behaviour can have spillover effects, negative or positive. On the one hand, producing renewable energy with their solar panels, people might feel that they are personally contributing to the fight against climate change, and therefore worry less about the environment. On the other hand, committing themselves to this fight, the cognitive dissonance theory (Festinger, 1957) would predict that they might be even more concerned than before.

I test whether solar panels affect environmental attitudes with data from the SOEP, which measures how worried the respondents are about the environment and the consequences from climate change. Both variables are measured with a three-point scale as 1 = *Very Concerned*, 2 = *Somewhat Concerned*, and 3 = *Not Concerned At All*. I have reversed coded this variable

so that the higher values indicate increasing concern, and re-run the models in Table 1 with these two concerns as the dependent variables.

Table A5 presents the regression models, returning results similar to those in the main text. The coefficient is positive and significant in the pooled model, but this significance disappears in the fixed-effect models. This suggests that those who are more concerned about the environment or climate change are more likely to adopt solar panels, but the solar panels alone do not cause a significant change in these environmental attitudes.

Table A5: Effect of solar system ownership on environmental attitudes

Notes: Standard errors are in parentheses. Control variables include education, head of households, unemployment, household income, households with children, house owners, and geographical regions. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Voting Intentions

Existing evidence suggests that, overall, policy feedback effects are stronger for political participation than for political attitudes (Campbell, 2012; Larsen, 2019). Accordingly, if there is any effect of solar panels on owners, we might be more likely to find it in, for example, owners' likelihood to vote rather than their interest in politics, or their likelihood to vote for green parties rather than their identification with these parties.

To test whether solar panels affect participation, I use the SHP item that measures voting intention. Specifically, it asks 'If there was an election for the National Council tomorrow, for which party would you vote?' I code *Electoral Turnout* as 0 if respondents indicated that they 'Wouldn't vote' or would vote 'For no party.' Otherwise, it is coded as 1. Similarly, I code *Vote: Greens* as 1 if they indicated the Green Party of Switzerland, Socialist Green Alternative, or the Green Liberal Party of Switzerland as their intended vote choice, and as 0 if they indicated a party other than these three parties.

Table A6 presents the regression models, returning results similar to those reported in the main text: The best estimates are substantively and statistically insignificant. In other words, solar panel ownership does not seem to have a meaningful effect on voting intentions either.

Table A6: Effect of solar system ownership on intended voting behaviour

	Electoral Turnout (1 - 3)			Vote: Greens (4 - 6)		
	(1)	(2)	(3)	(4)	(5)	(6)
Solar Panel	0.02 (0.02)	-0.004 (0.02)	-0.001 (0.02)	-0.001 (0.02)	-0.003 (0.03)	-0.001 (0.03)
FEs—Individuals	No	Yes	Yes	No	Yes	Yes
FEs—Waves	No	Yes	Yes	No	Yes	Yes
Controls	No	No	Yes	No	No	Yes
Cl. SEs—Individuals	Yes	No	No	Yes	No	No
Cl. SEs—Households	Yes	Yes	Yes	Yes	Yes	Yes
Observations	41,800	41,800	38,905	41,800	41,800	38,905
R ²	0.0001	0.69	0.69	0.0000	0.72	0.72
Adjusted R ²	0.0000	0.57	0.57	-0.0000	0.61	0.61

Notes: Standard errors are in parentheses. Control variables include education, head of households, unemployment, household income, households with children, house owners, and geographical regions. * $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.
